# The problem

Today I read a book about we can do cast-down in template, so I write this to test:

```
1  template<bool _Test, class _Type = void>
2  struct enable_if {};
3
4  template<class _Type>
5  struct enable_if<true, _Type> {
6      typedef _Type type;
7  };
8
9  class A {};
10 class B : A {};
11
12 template<typename T>
13 struct traits { static int const value = false; };
14
15 template<>
16 struct traits<A> { static int const value = true; };
17
18 template<typename T>
19 void f(T, typename enable_if<traits<T>::value>::type* = 0) {}
20
21 template<>
22 void f<A>(A, enable_if<traits<A>::value>::type*) {}
23
24
25
26 template<typename T>
27 class BB {};
28
29 template<typename T>
```

```

30  class DD : public BB<T> {};
31
32  template <typename T> void ff(BB<T>) {};
33
34  int main(int argc, char * argv[])
35  {
36      A a; B b;
37      DD<long> dd;
38      //f(b);
39      ff(dd);
40  }

```

It is strange when f it don't allow my specified f<A>` .

But in ff it allowed ff<BB<long>>` .

Tested under VC10 and GCC3.4

## My answer to the problem

Let's think ourself as compiler to see what happened there.

Define mark # : A#B is the instantiated result when we put B into the parameter T of A<T> .

## First we discuss ff

```

1  DD<long> dd;

```

After this sentence, the compiler saw the instantiation of DD<long> , so it instantiate DD#long , and also BB#long .

```
1 ff(dd);
```

This sentence required the compiler to calculate set of overloading functions.

Step 1 we need to infer  $T$  of  $ff<T>$  from argument  $DD\#long \rightarrow BB<T>$  . Based on the inference rule:

Argument with type :code:`class\_template\_name<T>` can be use to infer :code:`T` .

So compiler inferred  $T$  as  $long$  . Here if it is not  $BB$  but  $CC$  which is complete un-related, we can also infer, as long as  $CC$  is a template like  $CC<T>$  .

Step 2 Template Specialization Resolution. There is only one template here so we matched  $ff<T>$  .

Step 3 Template Instantiation

After inferred  $long \rightarrow T$  , compiler instantiated  $ff\#long$  .

Set of available overloading functions :  $\{ff\#long\}$

Then overloading resolution found the only match  $ff\#long$  , checked its real parameter  $DD\#long$  can be down-cast to formal parameter  $BB\#long$  .

## Then we discuss f

```
1 f(b);
```

Calculate set of overloading functions.

Step 1 infer all template parameters for template  $f$  . According to inference rule:

Parameter with type T can be used to infer T 。

So  $B \rightarrow T$  is inferred.

Step 2 Template Specialization Resolution.

Here B is not A so we can not apply specialization of  $f\langle A \rangle$  , remaining  $f\langle T \rangle$  as the only alternative.

Step 3 Template Instantiation.

When we put B into  $f\langle T \rangle$  to instantiate as  $f\#B$  , we need to instantiate  $\text{traits}\#B`$  .

There is no specialization for B so we use template  $\text{traits}\langle T \rangle$  ,  $\text{traits}\#B::\text{value}=\text{false}$  , so  $\text{enable\_if}\#false$  didn't contains a type , an error occurred.

The only template is mismatch, available overloading functions is empty set. So we got an error.
