The problem

Today I read a book about we can do cast-down in template, so I write this to test:

```
1 template <bool _Test, class _Type =
void>
2 struct enable_if { };
3
4 template < class _Type >
5 struct enable_if < true, _Type > {
6     typedef _Type type;
7 };
8
9 class A { };
```

```
10 class B : A { };
11
12 template <typename T>
13 struct traits { static int const val
ue = false; };
14
15 template <>
16 struct traits<A> { static int const
value = true; };
17
18 template <typename T>
19 void f(T, typename enable if<traits<T
>::value>::type* = 0) { }
20
21 template <>
22 void f<A>(A, enable if<traits<A>::va
lue>::type*) { }
23
24
25
26 template <typename T>
27 class BB {};
28
29 template <typename T>
30
   class DD : public BB<T> {};
31
32
   template <typename T> void ff(BB<T>)
{};
33
34 int main(int argc, char * argv[])
35
   {
36
     A a; B b;
```

```
37 DD<long> dd;
38 //f(b);
39 ff(dd);
40 }
```

It is strange when f it don't allow my specified f<A>`.

Butin ff itallowed ff<BB<long>>`.

Tested under VC10 and GCC3.4

My answer to the problem

Let's think ourself as compiler to see what happened there.

Define mark #: A#B is the instantiated result when we put B into the parameter T of A<T> .

First we discuss ff

1 DD<long> dd;

After this sentense, the compiler saw the instantiation of DD<long> , so it instantiate DD#long , and also BB#long .

```
1 ff(dd);
```

This sentense required the compiler to calculate set of overloading functions.

Step 1 we need to infer T of ff<T> from argument DD#long -> BB<T> . Based on the inference rule:

Argument with type :code:`class_tem plate_name<T>` can be use to infer :code:`T``.

So compiler inferred T as long. Here if it is not BB but CC which is complete un-related, we can also infer, as long as CC is a template like CC<T>.

Step 2 Template Specialization Resolution. There is only one template here so we matched ff<T> .

Step 3 Template Instantiation

After inferred long -> T , compiler instantiated ff#long .

Set of available overloading functions: {ff#long}

Then overloading resolution found the only match ff#long`, checked its real parameter DD#long can be down-cast to formal parameter BB#long.

Then we discuss f

```
1 f(b);
```

Calculate set of overloading functions.

Step 1 infer all template parameters for template f . According to inference rule:

Parameter with type T can be used to infer T $_{\circ}$

So B -> T is inferred.

Step 2 Template Specialization Resolution.

Here B is not A so we can not apply specialization of f<A> , remaining f<T> as the only alternative.

Step 3 Template Instantiation.

When we put B into f<T> to instantiate as f#B, we need to instantiate traits#B`.

There is no specialization for B so we use template traits<T> , traits#B::value=false , so enable_if#false didn't contains a type , an error occurred.

The only template is mismatch, available overloading functions is empty set. So we got an error.
